To this class of deposits I have applied the term frontal apron. This plain region has normally a width of from one to six miles and surface very nearly horizontal. Most commonly this surface inclines gently backward towards the moraine for the distance of a mile or more from the front. Then from indistinct summits it declines at the rate of three or four feet to the mile away from the morainal accumulation. I have no question that the greater part if not the whole of these deposits were formed beneath the surface of a water area. Along the coast it is evident that this water...
